Abstract

Gestational diabetes mellitus (GDM) represents glucose levels in the high end of the population distribution during pregnancy. GDM carries a high risk of adverse outcomes such as perinatal outcomes and a longer-term risk of obesity and glucose intolerance in offspring. Mothers with GDM have an excess of hypertensive disorders during pregnancy and a high risk of diabetes mellitus after that. This study aimed to evaluate the influence of hypoxia status, haematological parameters, cord blood lactate, and birth weight of infants on GDM and its complications. The study was conducted on 100 pregnant women having Gestational Diabetes Mellitus (GDM), and the control population consists of 50 normal pregnancies. Samples included in this study were foetal cord blood and maternal blood. Parameters such as blood gases, lactate, haemoglobin, RBC count, red cell indices, and fetal birth weight were determined. No suggestive changes were found in pH of GDM neonates when compared to the healthy foetus. GDM offspring, when compared to the normal, showed a significant decrease in pO₂ and pCO₂. A relative reduction in O₂ saturation and O₂ content in GDM foetus when compared to a healthy foetus. Lactate level is significantly increased in GDM neonates when correlated to the control group. There is a striking change in haemoglobin, RBC count, total WBC count, MCV and MCH in GDM. The results also suggest a correlation of cord blood Hb, cord blood PCV and Cord blood pO₂ with the birth weight of infants. Lower oxygen saturation and oxygen content and increased lactate concentrations in offspring of GDM mothers indeed emulate intensified fetal metabolism as an outcome of hyperglycaemia and hyperinsulinemia, and therefore these fetuses demand constant supervision at term and during delivery.

Keywords: Gestational diabetes mellitus, Umbilical arterial cord blood, Hypoxic-ischemic event.

Introduction

Gestational diabetes mellitus (GDM) is defined as impaired glucose tolerance with onset or first recognition during pregnancy. The incidence of GDM varies between populations ranging from 1.7% to 11.6%.¹ According to the International Diabetes Federation, 21 million pregnancies were affected by diabetes during the year 2013. India has the second largest number of subjects having diabetes in the world (62.4 million), and this number is expected to reach 100 million by the year 2030.²

Women with Gestational uncontrolled diabetes can lead to a huge baby that can increase the risk of birth injury, hypoxia, brain ischemia, brachial plexus injury, Erb's palsy or shoulder dystocia and cerebral palsy. Complications for the fetal growth are macrosomia, hyperbilirubinemia, respiratory distress syndrome, polycythemia, neonatal jaundice and preterm birth. Not only that, infants resolved to maternal diabetes had an elevated risk of diabetes and obesity in infancy and adolescence.³

The evolving foetus depends on the mother for the placental interchange of oxygen and carbon dioxide. This in turn, depends on sufficient maternal blood gas concentrations, uterine blood supply, and placental and foetal gas exchange. Fetal hyperglycemia and

subsequent hyperinsulinemia stimulate aerobic metabolism that may further intensify the fetal oxygen demand.⁴ On the occasion of anoxic/hypoxic-ischemic events, Hypoxic Ischemic Encephalopathy (HIE) occurs which may lead to permanent brain damage to the baby. The result of a hypoxic-ischemic encephalopathy condition often leads to cerebral palsy or seizure disorders.⁵

The most elegant approach to assess anoxic or a hypoxic-ischemic event is the umbilical cord arterial blood analysis is that as it arrives from the baby. The most unbiased way of evaluating fetal metabolic condition at birth is the Umbilical cord arterial blood analysis. This appraisal soon after delivery conveys the newborn's acid-base status.⁶ All high-risk deliveries are now suggested to evaluate the cord blood analysis by both the British and American Colleges of Obstetrics and Gynaecology. Hence the present study was carried out to find the influence of hypoxia status, haematological parameters, cord blood lactate, and birth weight on GDM and its complications.

Materials and Methods

A case-control study was conducted at MES Medical College Perinthalmanna, Kerala. The test populations were the pregnant women who attended the

Gynecology & Obstetrics department of MES Medical College, who has been diagnosed to have GDM.

Inclusion Criteria: Age group between 19 to 38 years and both under diet control and insulin therapy are included in the test population. The control group will be the pregnant women with normal glucose level and uncomplicated pregnancy.

Exclusion Criteria: Pregnant women with overt diabetes mellitus, with unknown glycemic status and deliveries before the period of viability of fetus will be excluded.

Study Design: Test population consists of 100 pregnant women with GDM and control population consists of 50 normal pregnancies. The study was performed after obtaining clearance from the institutional ethics committee. Before the collection of samples, informed consent was obtained. The screening test for the GDM was carried out according to the WHO recommended protocol which is followed in the MES Medical College, Perinthalmanna. A maternal venous blood sample was collected before delivery and transferred into EDTA bottles. A segment of umbilical cord was double clamped immediately after delivery and before first breath, excised. Umbilical arterial blood samples were taken in heparinized syringes and EDTA tubes. The heparinised samples are analyzed by ABG analyzer (I-stat) within 30 minutes after birth for pH, pO₂,

pCO₂, and lactate. The EDTA samples of maternal and cord blood were analysed for haematological parameters like haemoglobin (Hb), RBC count and Red cell indices.

Statistical Analysis

Statistical analysis was done by entering the mean and SD values in MYSTAT 12 (SYSTAT) software. The results were expressed as a mean and standard deviation. The P value was used to compare the parameters between the two groups. A un-paired t-test was selected for finding the p-value. The P value less than 0.05 are considered as significant.

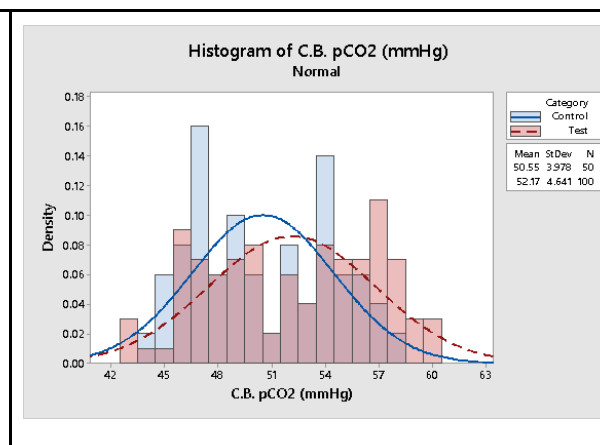

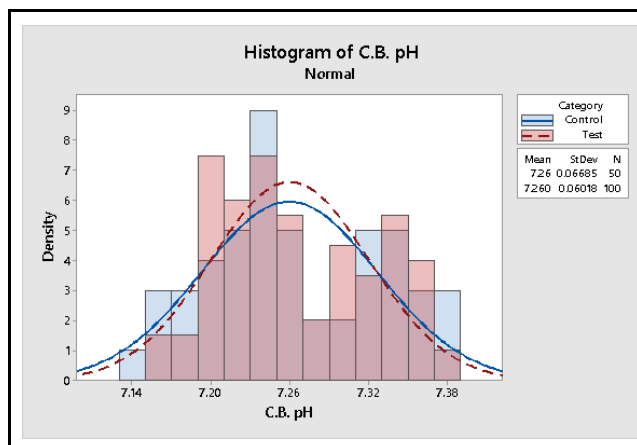

Results

The results and findings are given in tables and figures. No suggestive changes were found in pH of GDM neonates when compared to the healthy fetus. GDM offspring, when compared to the normal, showed a significant decrease in pO₂ and pCO₂. A relevant reduction in O₂ saturation and O₂ content in GDM foetus when compared to a normal embryo (Table 1). The present study indicates that lactate level is significantly increased in GDM neonates when compared to the control group.

Table 1: Respiratory gases, acid-base balance in normal (control) and GDM (test)

Parameters	Control (n=50)	Test (n=100)	t	p
C.B. pH	7.26 ± 0.07	7.26 ± 0.06	-0.037	0.971
C.B. pCO ₂ (mmHg)	50.55 ± 3.98	52.17 ± 4.64	-2.118	<0.05*
C.B. pO ₂ (mmHg)	27.04 ± 2.5	23.73 ± 2.15	8.382	<0.01**
C.B. O ₂ Sat (%)	66.37 ± 3.96	47.01 ± 7.08	17.955	<0.01**
C.B. Lactate (mmol/L)	2.05 ± 0.74	2.72 ± 0.58	-6.005	<0.01**

All Values are mean ± Standard Deviation. n=Total Number of subjects. The statistical test used is t-test. *Significant at p<0.05 and ** Significant at p<0.01.

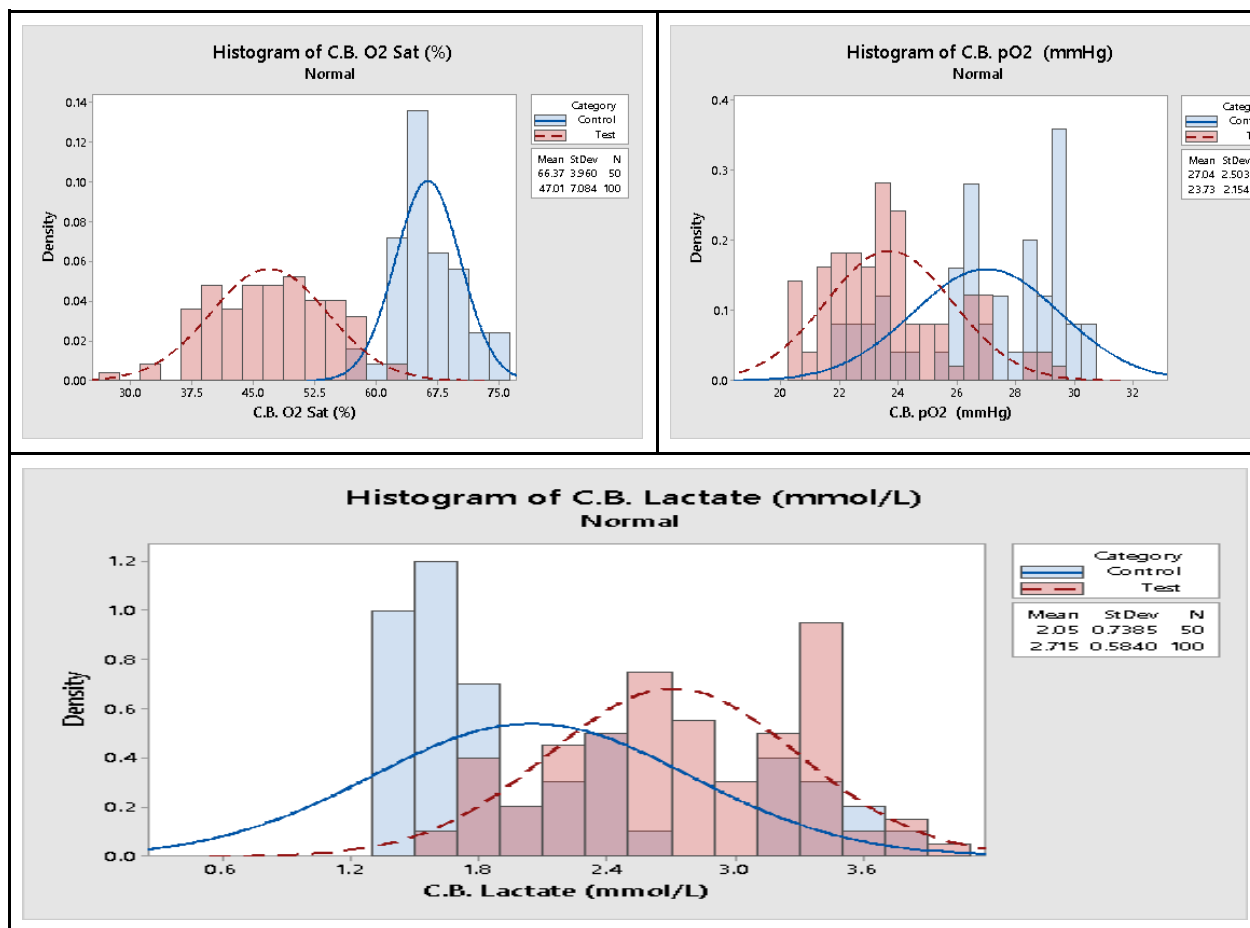

Fig. 1: Respiratory gases, acid-base balance in normal (control) and GDM (test)

There is a significant change in haemoglobin, RBC count, total WBC count, MCV and MCHC in GDM when compared to healthy population (Table 2). But no

significant change was noted in lymphocyte, monocyte, eosinophil, neutrophil, HCT and MCHC of test population compared to the normal group.

Table 02: Distribution of blood indices between the test and control groups

Parameters	Control (n=50)	Test (n=100)	t	p
M. Hb (g/dL)	11.86 ± 0.99	11.6 ± 0.5	2.134	<0.05*
M. RBC (K/μL)	4.78 ± 0.42	4.94 ± 0.41	-2.142	<0.05*
M.WBC (Cells/μL)	7386 ± 1873.55	8217 ± 1258.11	-3.219	<0.01**
M. lymphocyte (%)	36.32 ± 4.75	35.38 ± 5.33	1.055	0.293
M. monocyte (%)	4.02 ± 1.25	4.14 ± 1.44	-0.503	0.616
M. eosinophil (%)	3.66 ± 1.14	3.52 ± 1.34	0.634	0.527
M. neutrophil (%)	56 ± 4.42	56.96 ± 5.11	-1.133	0.259
M.HCT (%)	35.52 ± 3.16	34.98 ± 1.79	1.328	0.186
M. MCV (fL)	74.74 ± 8.69	71.37 ± 7.13	2.532	<0.05*
M. MCH (pg)	24.95 ± 2.73	23.72 ± 2.3	2.891	<0.01**
M. MCHC (%)	33.42 ± 0.79	33.25 ± 0.84	1.204	0.23

All Values are mean ± Standard Deviation. n=Total Number of subjects. The statistical test used t-test.
*Significant at p<0.05 and ** Significant at p<0.01.

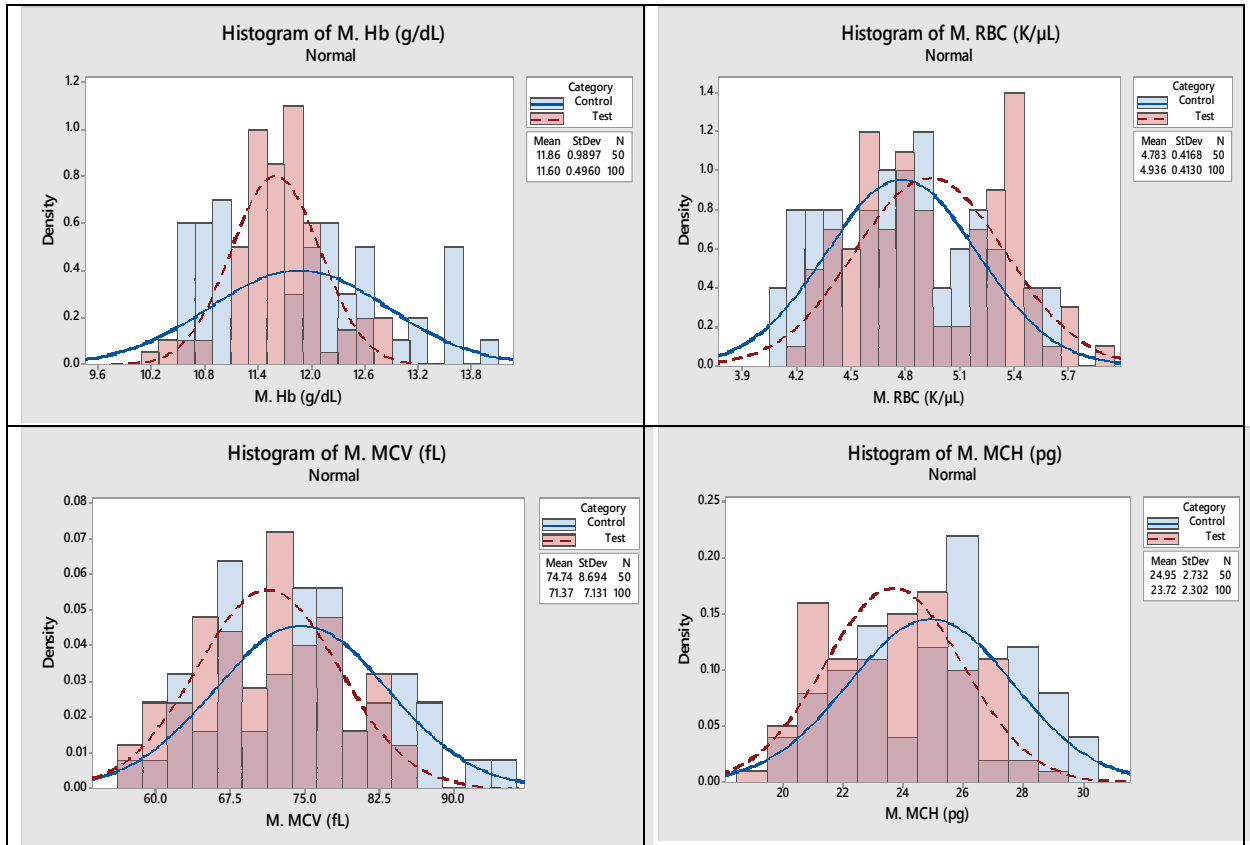

Fig. 2: Haematology parameters in normal (control) and GDM (test)

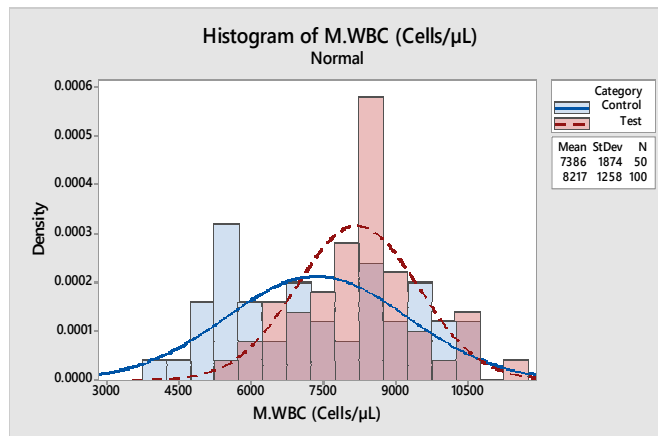

Fig. 3: White blood cell count in normal (control) and GDM (test).

The correlation of birth weight with cord blood gas and cord blood haematological parameters were tested to find the role of GDM on the birth weight of infants

(Table 3). The data showed a significant negative correlation between cord blood Hb values and cord blood PCV and pO₂ levels with the birth weight of infants.

Table 3: Correlation of birth weight with blood gas and haematological parameters

Parameters	Birth weight (Kg)
C.B. pH	-0.071 (0.387)
C.B. pCO ₂ (mmHg)	-0.051 (0.535)
C.B. pO ₂ (mmHg)	-.179* (<0.05)
C.B. O ₂ Sat (%)	-0.146 (0.074)
C.B. Lactate (mmol/L)	0.047 (0.564)

C.B. Hb (g/dL)	-.245** (<0.01)
C. B. PCV (%)	-.222** (<0.01)
C.B. RBC (K/ μ L)	0.015 (0.858)
C.B. MCV (fL)	-0.134 (0.102)
C.B. MCH (pg)	-0.146 (0.074)
C.B. MCHC (%)	-0.049 (0.552)
Statistics used are the Pearson correlation. All values are the correlation coefficient (r) and significance level (p). ** Correlation is significant at p<0.01 level and * Correlation is significant at p<0.05 level

Discussion

Gestational diabetes mellitus (GDM) is a severe and neglected threat to maternal and child health. Many women with GDM experience pregnancy-related complications including high blood pressure, large birth weight babies and obstructed labor. Approximately half of women with a history of GDM go on to develop type 2 diabetes within five to ten years after delivery. It is approximated that 4 million women are affected by GDM in India at any given point in time.⁷ According to the study conducted at Tertiary Health Centre in Northern India by Dahiya K, et al. regarding the maternal and fetal outcome in Gestational Diabetes Mellitus were polyhydramnios and the increased rate of caesarean sections. Babies born to GDM mothers had a higher incidence of metabolic complications and macrosomia.⁸

Pinnock C et al. reported that the placenta is bound for the transfer of oxygen and carbon dioxide to and from the developing fetus. Oxygen partial pressure gradient between maternal blood in the intervillous space and fetal blood in the umbilical arteries is culpable for the oxygen transfer. Carbon dioxide also crosses the placenta readily by passive diffusion.⁹ The current study results showed that the offspring of gestational diabetic mothers present significant differences in pO₂ and pCO₂ when compared to normal fetuses at delivery. A study conducted by Jahromi BN et al. observed the neonatal umbilical artery blood gas values between offspring of the diabetic mothers and normal mothers which showed higher pCO₂ values in the neonates of the diabetic mothers when compared with the control group.¹⁰ These changes are the crucial and important evidence that prove the occurrence of foetal hypoxia in GDM cases. Lower oxygen saturation and oxygen content and increased level of lactate concentration were found in GDM neonates when compared to the foetus of normal mothers. Hiden U, et al. Suggested that in diabetes, as a result of the hyper vascularization gross placental structure may be altered.¹¹ A potential reduction of placental oxygen transport may result due to greater placental capillary surfaces. Reduced oxygen transport from the placenta and further impaired oxygen delivery may result, due to the reduction of uteroplacental blood flow in diabetic pregnancies especially when maternal hyperglycaemia is more pronounced. GDM fetus accommodates to the hyperglycemia in the utero-environment by developing insulin production, which consequently leads to fetal hyperinsulinemia.¹²

Increasing of lactate concentration occurs because of the initiation of anaerobic glycolysis due to hypoxia. It has since become extensively preferred that umbilical cord blood gas analysis can present significant data about the past, current and the prospective condition of the infant. The haemoglobin levels in GDM mothers' showed decreased value. West JB sighted that umbilical cord blood gas analysis can give an intimation of prior

fetal hypoxic stress.¹³ These findings are strengthened by the results of the study conducted by Molnar et al.¹⁴ They also showed a marked decrease in oxygen content, oxygen saturation and a significant increase in lactate concentrations. Lower oxygen saturation and oxygen content and increased lactate concentrations in offspring of GDM mothers indeed emulate intensified fetal metabolism as an outcome of hyperglycaemia and hyperinsulinemia, and therefore these fetuses demand constant supervision at term and during delivery. Belai et al. conducted the study of cord blood pH, pO₂ and pCO₂ in high-risk pregnancies including gestational diabetes using umbilical arterial cord blood analysis.¹⁵ Significant association of umbilical cord arterial blood gas pH, pO₂ and pCO₂ values and the adverse neonatal outcome was found.

Our study shows a striking decrease in haemoglobin, RBC count, and MCH in GDM when compared to normal, but the change in MCV, MCHC value was not significantly different compared to the normal. This was comparable to the study conducted by Mercelina et al., who found an indicative reduction in cord blood Hemoglobin, Red blood corpuscles, Packed cell volume, Blood indices in the infants of gestational diabetic mothers.¹⁶ The results were also suggesting a correlation of cord blood Hb, cord blood PCV and Cord blood pO₂ with the birth weight of infants. In addition to this, the current study also evaluated the correlation between birth weight and biochemical parameters such as cord blood Hb, C.B. pH, PCO₂, PO₂, O₂ sat, lactate, RBC, MCV, MCH, PCV and MCHC, We observed a statistically negative correlation of body weight with PCV, Hb and PO₂ and there was no correlation observed with other parameters. A similar observation was obtained in Anne Vambergue et al. and Metzger BE et al.^{17,18} These studies have observed a negative correlation of these parameters with body weight. The result indicates that the body weight and fetal Hb, partial pressure of oxygen and Packed cell volume have some direct relationship.

Conclusion

No suggestive changes were found in pH of GDM neonates when compared to the normal foetus (N). GDM offspring, when compared to the normal, showed a significant decrease in pO₂ and pCO₂. A relative reduction in O₂ saturation and O₂ content in GDM foetus when compared to a normal foetus. The present study indicates that lactate level is significantly increased in GDM neonates when compared to the control group. There is a striking change in haemoglobin, RBC count, total WBC count, MCV and MCH in GDM when compared to the normal group.
